Preface

Automated process control offers so many advantages over manual control that the majority of today’s industrial processes use it to some extent. Breweries, wastewater treatment plants, mining facilities, and the automotive industry are just a few industries that benefit from automated process control systems.

Maintaining process variables such as pressure, flow, level, temperature, and pH within a desired operating range is of the utmost importance when manufacturing products with a predictable composition and quality.

The Instrumentation and Process Control Training System, series 353X, is a state-of-the-art system that faithfully reproduces an industrial environment. Throughout this course, students develop skills in the installation and operation of equipment used in the process control field. The use of modern, industrial-grade equipment is instrumental in teaching theoretical and hands-on knowledge required to work in the process control industry.

The modularity of the system allows the instructor to select the equipment required to meet the objectives of a specific course. Two mobile workstations, on which all of the equipment is installed, form the basis of the system. Several optional components used in pressure, flow, level, temperature, and pH control loops are available, as well as various valves, calibration equipment, and software. These add-ons can replace basic components having the same functionality, depending on the context. During control exercises, a variety of controllers can be used interchangeably depending on the instructor’s preference.

We hope that your learning experience with the Instrumentation and Process Control Training System will be the first step toward a successful career in the process control industry.

Preface

Do you have suggestions or criticism regarding this manual?

If so, send us an e-mail at did@de.festo.com.
The authors and Festo Didactic look forward to your comments.
To the Instructor

You will find in this Instructor Guide all the elements included in the Student Manual together with the answers to all questions, results of measurements, graphs, explanations, suggestions, and, in some cases, instructions to help you guide the students through their learning process. All the information that applies to you is placed between markers and appears in red.

Accuracy of measurements

The numerical results of the hands-on exercises may differ from one student to another. For this reason, the results and answers given in this manual should be considered as a guide. Students who correctly performed the exercises should expect to demonstrate the principles involved and make observations and measurements similar to those given as answers.

Equipment installation

In order for students to be able to perform the exercises in the Student Manual, the Process Control Training Equipment - Temperature must have been properly installed, according to the instructions given in the user guide Familiarization with the Instrumentation and Process Control System - Temperature, part number 86008-E.
Sample Exercise

Extracted from

the Student Manual

and the Instructor Guide
When you have completed this exercise, you will be familiar with three different methods for tuning your controller and you will have gained experience using at least one of them on a temperature process.

The Discussion of this exercise covers the following points:

- Recapitulation of relevant control schemes
- Tuning with the trial-and-error method
- Tuning with the ultimate-cycle method
  - Quarter-amplitude decay ratio.
- Limits of the ultimate-cycle method
- The open-loop Ziegler-Nichols method

This exercise introduces three control schemes and puts them to use in a temperature process loop. This allows a comparative analysis of the different schemes in terms of efficiency, simplicity, and applicability to various situations. An intuitive method to tune controllers is also presented.

Recapitulation of relevant control schemes

A controller in proportional mode (P mode) outputs a signal \( m(t) \) – manipulated variable which is proportional to the difference between the target value (SP: set point) and the actual value of the variable \( c(t) \) – controlled variable. This simple scheme works well but typically causes an offset. The only parameter to tune is the controller gain \( K_c \) (or the proportional band \( PB\% = 100\%/K_c \) if your controller uses this parameter instead).

A controller in proportional/integral mode (PI mode) works in a fashion similar to a controller in P mode, but also integrates the error over time to reduce the residual error to zero. The integral action tends to respond slowly to a change in error for large values of the integral time \( T_i \) and increases the risks of overshoot and instability for small values of \( T_i \). Thus, the two parameters which require tuning for this control method are \( K_c \) (or \( PB\% \)) and \( T_i \) (or the integral gain, defined as \( G_i = 1/T_i \)).

A controller in proportional, integral, and derivative mode (PID mode) incorporates the three control actions into a single polyvalent and powerful control scheme. The addition of derivative action to the PI mode covered in the previous exercise results in the capacity to attenuate overshoots to some extent, but adds the risk of instability if the process is noisy.

Tuning a controller in PID mode requires careful adjustment of the proportional gain \( K_c \), the integral time \( T_i \), and the derivative time \( T_d \) to properly address
the control requirements of the process. In some circumstances, the controller output must not be zero when the error is null. In these cases, a bias ($b$), also known as manual reset, must be set.

The on-off control mode is the simplest control scheme available. It involves either a 0% or a 100% output signal from the controller based on the sign of the measured error. The option to add a dead band is available with most controllers to reduce the oscillation frequency and prevent premature wear of the final control element. There are no parameters to specify for this mode beyond a set point and dead band parameters. Note that it is possible to simulate an on-off mode with a controller in P mode for a large value of $K_c$ (or a very small $PB\%$).

**Tuning with the trial-and-error method**

The trial-and-error method of controller tuning is a procedure for adjusting the P, I, and D parameters until the controller is able to rapidly correct its output in response to a step change in the error. This correction is to be performed without excessive overshooting of the controlled variable.

This method is widely used because it does not require the characteristics of the process to be known, and it is not necessary to bring the process into a sustained oscillation. Another important aspect of this method is that it is instrumental in developing an intuition for the effects of each of the tuning parameters.

However, the trial-and-error method can be daunting to perform for inexperienced technicians because a change in tuning constant tends to affect the action of all three controller terms. For example, increasing the integral action increases the overshooting, which in turn, increases the rate of change of the error and then increases the derivative action. A structured approach and experience help in obtaining a good tuning relatively quickly without resorting to involved calculations.

A good trial-and-error method is to follow a geometrical progression in the search for optimal parameters. For example, multiplying or dividing one of the tuning parameters by two at each iteration can help you converge quickly toward an optimal value of the parameter.

**A procedure for the trial-and-error method**

The trial-and-error method is performed using the following procedure (also refer to Figure 2-25 and Figure 2-26 for PI control):

1. Set the controller in the mode you want to use: P, PI, PD, or PID. Follow the instructions to adjust every parameter relevant to the mode you are using. Note that, if your controller allows doing so, you can use the PID mode to perform any of the modes by simply setting the parameters to appropriate values (e.g. $T_d = 0$ for PI mode).

**Adjusting the P action**

2. With the controller in manual mode, turn off the integral and derivative actions of the controller by setting $T_i$ and $T_d$ respectively to the largest possible value and 0.
3. Set the controller gain $K_c$ to an arbitrary, but small, value, such as 1.
4. Place the controller in the automatic (closed-loop) mode.
5. Make a step change in the set point and observe the response of the controlled variable. The set point change should be typical of the expected use of the system.

Since the controller gain is low, the controlled variable will take a relatively long time to stabilize (i.e., the response is likely to be overdamped).

6. Increase $K_c$ by a factor of 2 and make another step change in the set point to see the effect on the response of the controlled variable.

The objective is to find the value of $K_c$ at which the response becomes underdamped and oscillatory. This is the ultimate controller gain. Keep increasing $K_c$ by factors of 2, performing a set point change after each new attempt, until you observe the oscillatory response.

Once the ultimate controller gain is reached, revert back to the previous value of $K_c$ by decreasing the controller gain by a factor of 2. The P action is now set well enough to add another control action if required.

**Adjusting the I action**

7. Start bringing in integral action by setting the integral time $T_i$ at an arbitrarily high value. Decrease $T_i$ by factors of 2, making a set point change after each setting.

Do so until you reach a value of $T_i$, at which the response of the controlled variable becomes underdamped and oscillatory. At this point, revert back to the previous value of $T_i$ by increasing $T_i$ to twice its value.

The I action is now set and you can now proceed to the adjustment of the D action, if required.

**Adjusting the D action**

8. Start bringing in derivative action by setting the derivative time at an arbitrarily low value. Increase $T_d$ by factors of 2, making a set point change after each setting.

Do so until you reach the value of $T_d$ that gives the fastest response without amplifying the overshot or creating oscillation.

The D action is now set.

**Fine-tuning of the parameters**

9. Fine-tune the controller until the requirements regarding the response time and overshooting of the controlled variable are satisfied.
With the controller in manual mode, turn off the integral and derivative actions. Set the controller gain to 1.0.

Place the controller in automatic mode.

Make a step change in the set point.

Is the process response underdamped and oscillatory?

No

Increase the controller gain to twice its value.

Yes

Set the gain to halfway between the actual gain and the previous gain.

Bring in the integral action by setting the integral time at a high value.

Make a step change in the set point.

Is the process response underdamped and oscillatory?

No

Decrease the integral time by a factor of 2.

Yes

Set the integral time to halfway between the actual time and the previous time.

Bring in the derivative action by setting the derivative time at a low value.

Make a step change in the set point.

Is the process response longer and is overshooting amplified?

No

Increase the derivative time to twice its value.

Yes

Reduce the derivative time to obtain the fastest response without overshooting amplification.

Fine-tune the controller to meet the response requirements.

Figure 2-25. Trial-and-error tuning method.
A complementary approach to trial-and-error tuning

Another, more visual approach is to use Figure 2-26 to assist you in tuning your controller. The figure presents responses of a PI process to a step change for different combinations of parameters. A good tuning is shown in the center of the figure for ‘optimal’ $K_c$ and $T_i$ parameters. The tuning in the center is not necessarily the most appropriate for the process you want to control; but the response shown is a good target for a rough first tuning.

The figure also shows responses for detuned parameters (both above and below the ‘optimal’ $K_c$ and $T_i$). Comparing the response you obtain for your system with the detuned responses in the figure tells you in which direction to change $K_c$, $T_i$, or both to converge towards the center case. Changing the parameters by a factor of two at every step until you get very close to the optimal value is a good method to converge rapidly.

If required, derivative action can then be added to the control scheme by following step 8 of the trial-and-error method. Then, fine-tune the parameters to optimize the control and to meet the specific requirements of your process.

Tuning with the ultimate-cycle method

The ultimate-cycle tuning method is one of the first heuristic methods suggested by Ziegler and Nichols for tuning PID controllers (the method is consequently sometimes called the closed-loop Ziegler-Nichols method). The ultimate-cycle
tuning method is designed to produce quarter-amplitude decay in the controlled variable after a given step change in the set point. This method enables the operator to calculate the P, I, and D tuning constants required for P, PI, PD, or PID control of a process using two parameters of the process: the ultimate gain ($K_u$) and the ultimate period ($T_u$).

The ultimate gain $K_u$ is the largest value of $K_c$ in P-only control mode such that the process is still stable (albeit marginally), i.e., the system is in a continuous, sustained oscillation. The ultimate period $T_u$ is the period of the response when the gain is set to the ultimate gain.

The ultimate proportional band $PB_u$ can be used instead of $K_u$. It is then defined as the smallest value of $PB$ for which the process is stable.

$$PB\% = \frac{100\%}{K_c}$$
The ultimate-cycle tuning method follows this procedure:

1. With the controller in manual mode, turn off the integral and derivative actions so as to use only P mode.

2. Set the proportional gain $K_c$ at an arbitrary, but somewhat small, value, such as 1.

3. Place the controller in automatic (closed-loop) mode.

4. If the process starts to oscillate by itself, go to step 7. Otherwise, create a step change in the set point. The set point change should be typical of the expected use of the system.

5. If the process does not oscillate, increase the gain by a factor of 2.

6. Repeat steps 4 and 5 until the response becomes oscillatory.

7. Determine whether the oscillation is sustained—i.e., if it continues at the same amplitude without increasing or decreasing as in Figure 2-27c. If not, make small changes in the proportional gain until a sustained oscillation is achieved.

   **Note:** It is often necessary to wait for the completion of several oscillations before it can be determined if the oscillation is sustained.

The proportional gain, at which the sustained oscillation begins without causing saturation of the controller output, is the ultimate proportional gain, $K_u$. Note this value. Then note the period of the oscillation of the process, as shown in Figure 2-27c. This is the ultimate period, $T_u$.

8. Using the ultimate proportional gain and ultimate period, calculate the tuning constants of the controller as follows:

   **Table 2-2. Control parameters for the ultimate-cycle tuning method.**

</table>

Once the tuning constants of the controller are adjusted to the calculated values and the controller is returned in the automatic (closed-loop) mode, changes in the set point should produce a quarter-amplitude decay response. Optimization of the controller settings may require further fine-tuning.
Quarter-amplitude decay ratio

John G. Ziegler and Nathaniel B. Nichols, who were pioneers in control engineering, established a criterion to determine if a controller is appropriately tuned. This criterion is the quarter-amplitude decay ratio. It states that, for two successive oscillations, the amplitude of the second oscillation should be one fourth of the amplitude of the first oscillation.

![Diagram of Quarter-amplitude decay ratio]

Presence of a quarter-amplitude decay ratio in a response is a rough approximation for the optimal tuning of PID controllers. A controller is generally considered to be reasonably tuned when it satisfies this criterion; but fine-tuning may be required to adapt the controller response to a specific process control application.

The quarter-amplitude decay response is a compromise between an underdamped and an overdamped response. The process response is **overdamped** when the controlled variable slowly returns to the set point after the step change without overshooting it. The response is **underdamped** when the controlled variable quickly returns to the set point with one or more overshoots before stabilizing. An underdamped response often means that the controller reacts too aggressively to correct the error, thereby overdoing it.

**Limits of the ultimate-cycle method**

It is important to note that the formulas given above apply only for non-interacting ideal controllers. Other formulas must be used for series or non-interacting parallel controllers. Refer to the section entitled *Structure of controllers* on page 53 for details.
It is also important to stress that using the ultimate-cycle tuning method may be out of the question in processes where bringing the system into continuous oscillation could be dangerous or might cause damage. Instead, another method of tuning, such as the trial-and-error method or the open-loop step response method, should be used. The open-loop step response method is also known as the open-loop Ziegler-Nichols method.

The open-loop Ziegler-Nichols method

This method of controller tuning was developed in 1942 by John G. Ziegler and Nathaniel B. Nichols. It enables the operator to calculate the P, I, and D tuning constants required for P, PI, or PID control of a process based on the open-loop response of the process to a step change in the set point.

The open-loop step response method is performed according to the following procedure:

1. With the controller in open-loop mode, create a step change in controller output. The resulting change in controlled variable should be typical of the expected use of the system. Note that you can use a calibrator instead of the controller to create a step change.

2. Based on the response curve of the controlled variable, determine the process gain $K_p$, the dead time $t_d$, and the time constant $\tau$ of the process. Refer to Ex. 1-1 for a discussion about process parameters.

Calculate the value of the parameter $\kappa$

$$\kappa = \frac{\tau}{t_d K_p}$$

3. Using the process characteristics found in step 2, calculate the tuning constants of the controller as follows:

<table>
<thead>
<tr>
<th>Mode</th>

Once the tuning constants of the controller are adjusted to the calculated values and the controller is returned to the closed-loop mode, a typical change in the set point should produce the desired quarter-amplitude decay response. The controller should also be able to correct for load changes rapidly, without excessive overshooting or oscillation of the controlled variable. Note, however, that small readjustments of the P, I, and D tuning constants may be required to obtain the optimum controller setting.
It is important to note that the formulas given above apply only to non-interacting, ideal controllers. Other formulas must be used for series or non-interacting parallel controllers. Refer to the section titled Structure of controllers on page 53 for details.

An advantage of the open-loop step response method is that the process needs to be disturbed only once to obtain the required process characteristics. On the other hand, the determination of precise process parameters requires a few calculations and, often, some adjustments.

The Procedure is divided into the following sections:

- Setup and connections
- Tuning the controller
- Controlling a temperature process

**Setup and connections**

1. Verify that the emergency push button is wired so as to be able to cut the power in case of emergency. The Familiarization with the Training System manual covers the security issues related to the use of electricity with the system as well as the wiring of the emergency push button.

2. Make sure the 3531 system is properly set up to use the Heating/Cooling unit. The system should also be in its basic setup configuration.

3. Connect the equipment according to the piping and instrumentation diagram (PID) shown in Figure 2-29, and use Figure 2-30 to position the equipment correctly on the frame of the training system. To set up your system for this exercise, start with the basic setup presented in the Familiarization with the Training System manual and add the equipment listed in Table 2-4. Drives 3 and 4 and pumps 3 and 4 must be connected to the setup as explained in the Familiarization with the Training System manual even though they are not shown explicitly in Figure 2-29.

Note how a T-shaped connector is used to split the flow of water from HV2B between the heat exchanger and the three-way control valve. This setup allows stopping the flow of cold water in the heat exchanger using the control valve.

Figure 2-29. PID – Heat exchanger control.
4. Connect the pneumatic unit to a dry-air source with an output pressure of at least 700 kPa (100 psi).

5. Connect the I/P converter of the three-way control valve to the pneumatic unit. Use the low-pressure port to do so.

6. Do not power up the instrumentation workstation yet. Do not turn on the electrical panel or the heating/cooling unit before your instructor has validated your setup—that is not before step 11.
7. To perform control of your process, you must connect the output of your controller to the control valve and the temperature transmitter to the input of the controller. You must include the recorder in your connection. On channel 1 of the recorder, plot the signal from the controller output and on channel 2, plot the signal from the transmitter output. Be sure to use the analog input of your controller to connect the temperature transmitter. Refer to the manual of your controller for details on how to connect it to other devices.

8. Figure 2-31 shows how to connect the paperless recorder to your system to plot the control signal from the controller on channel 1 and the controller input on channel 2.

![Diagram of equipment connection]

Figure 2-31. Connecting the equipment to the recorder.

9. Before proceeding further, complete the following checklist to make sure you have set up the system properly. The points on this checklist are crucial elements for the proper completion of this exercise. This checklist is not exhaustive, so be sure to follow the instructions in the *Familiarization with the Training System* manual as well.

- Every piece of equipment used is secured to the station with the appropriate bolt-and-nut mechanism.
- The heat exchanger is properly installed on the station.
- The hand valves are in the positions shown in the PID:
  - Open valves: HV1A, HV1B, HV2A, HV2B, HV5A, and HV5B.
  - Closed valves: HV3A, HV3B, HV4A, and HV4B.
- The hand valves under the drip trays are in the positions specified in the *Familiarization with the Training System* manual:
  - Open valves: HV1A, HV1B, HV8A, and HV8B.
- The L port of the three-way control valve is fully open.
- The pneumatic connections are correct.
• The controller is properly connected to the temperature transmitter.
• The controller is properly connected to the three-way control valve.
• The paperless recorder is connected correctly to plot the calibrator signal on channel 1 and the temperature transmitter output on channel 2.

10. Ask your instructor to check and approve your setup.

11. Power up the electrical unit. This starts all electrical devices as well as the pneumatic devices.

    Adjust the pressure at the low-pressure port so 170 kPa (25 psi) is sent to the I/P converter of the control valve.

12. Start the drives 3 and 4 (pumps P3 and P4). These pumps make the water of the two tanks flow in the heating/cooling unit. Ensure the process fluid from each tank is circulating correctly, then power up the heating/cooling unit. Make sure valve HV7 is closed. Continue with the next steps while the water in each tank is respectively heating and cooling toward their temperature set points.

13. Test your system for leaks. Use drives 1 and 2 to make pumps P1 and P2 run at low speed to produce a small flow rate. Progressively increase the frequency output of drives 1 and 2 up to 30 Hz. Repair any leaks.

    Let drives 1 and 2 run at 30 Hz.

14. The temperature in the two tanks should be stable and at their respective set points by now. If this is not the case, identify the problem or wait until the temperatures of the tanks stabilize.

15. Test the three-way control valve with your controller in manual mode and make sure it is fully open on L for a 4 mA signal and fully open on U for a 20 mA signal.

16. Configure the paperless recorder so it displays and records the control signal to the three-way control valve on channel 1 and the process temperature on channel 2.

    The sampling rate of the paperless recorder should be set to 1 s. To do so, go in the Main Menu ► Setup ► Application ► Signal Group ► Group X (where X is the number of your active group, typically set to 1) ► Save Cycle ► 1 s.

17. Use the temperature transmitter to display the temperature measured by the RTD (TE1A) and to send the related 4-20 mA signal to your controller and
trend recorder. The RTD should be installed at the output of the heat exchanger, where the cooled water exits.

18. With the controller in manual mode, set the controller output to 100% to maximize the amount of cold water that circulates in the heat exchanger. Wait for the temperature to stabilize and record the transmitter output (the temperature) in percentage below.

TE1A output (100% controller output): ______________%  

TE1A output (100% controller output): 55% (about 26°C or 79°F)

19. Unplug the RTD from the temperature transmitter. After a few seconds, the transmitter should display the temperature measured by the thermocouple and it should send the associated 4-20 ma signal to the trend recorder. Record the temperature of the cold water output for a 100% controller output in percentage below:

Cold water temperature (100% controller output): ______________  

Cold water temperature (100% controller output): Approximately 58% (about 27°C or 80.5°F)

20. Plug the RTD back in place and be sure the paperless recorder displays the warm water flow temperature.

21. Set the controller output to 0% to stop the cold water flow in the heat exchanger. Wait for the temperature to stabilize, and record the transmitter output (the temperature) in percentage below.

TE1A output (0% controller output): ______________%  

TE1A output (0% controller output): Approximately 78% (about 33°C or 91°F)

22. Again, unplug the RTD from the temperature transmitter. After a few seconds, the transmitter should display the temperature measured by the thermocouple. Record the temperature of the cold water output for a 0% controller output in percentage below:

Cold water temperature (0% controller output): ______________  

Cold water temperature (0% controller output): Approximately 58% (about 27°C or 80.5°F)
23. Plug the RTD back in place and be sure the paperless recorder displays the warm water flow temperature.

**Tuning the controller**

24. The temperature process can be controlled using various control schemes (on-off, P, PI, PD, and PID). However, you are more likely to obtain good results using a controller set to the PI mode. Set your controller to this mode and adjust the parameters using the open-loop Ziegler-Nichols method.

Use the process characteristics obtained in the previous exercise for your calculations and note the parameters entered in the controller:

\[ K_c = \_\_\_\_\_\_\_\_\_ \]

\[ T_i = \_\_\_\_\_\_\_\_\_ \]

The Ziegler-Nichols method suggests the following relationships to obtain the parameters in PI mode:

\[ K_c = 0.9 \kappa \]

\[ T_i = 3.33 \tau_b \]

\[ \kappa = \frac{\tau}{\tau_b K_p} \]

Using the process characteristics obtained in the previous exercise \( (K_p = -0.575, \tau = 34 \text{ s}, \text{ and } \tau_b = 13 \text{ s}) \), we can calculate the parameters. Note that the results obtained are indicative only and are likely to differ.

\[ K_c = 4.089 \]

\[ T_i = 43.3 \text{ s} \]

25. Switch the controller to the automatic mode and have it maintain a set point of 70%.

26. Test your settings extensively by creating step changes in the controller set point (e.g., from 70% to 60%).

27. Does the open-loop Ziegler-Nichols method gives good results without further tuning of the controller parameters?

In this case, the results were acceptable. The precision and care invested in the measurement of process characteristics have a large impact. A fine-tuning remains almost always advantageous.
28. If the control is not satisfactory, fine-tune the controller parameters manually using Figure 2-26 to find the best PI parameters. If you had to change the controller parameters, note the new parameters below:

\[ K_c = \underline{\phantom{0000}} \]

\[ T_i = \underline{\phantom{0000}} \]

Controlling a temperature process

29. Once the controller is properly tuned, erase the internal memory of the paperless recorder. Wait a few seconds after the recorder is done rebooting, then perform a set point step change from 70% to 60%.

30. Wait for the value of the process variable to stabilize.

31. Once the system is at steady state, transfer the data from the paperless recorder to a computer or save it on a USB key. Follow the procedure in the Familiarization with the Training System manual to do so.

32. Stop the system.

33. Plot the process data using a spreadsheet software.

The graph obtained as the process underwent a 70-60% step change (past the 400 s mark) is provided below. Your results may vary.

34. Stop drives 1 and 2, and let the water drain out of the hoses.
35. Turn off the heating/cooling unit, then stop drives 3 and 4. Turn off the pneumatic unit and the electrical unit. Turn off your calibrator if one was used.

36. Store the equipment adequately, clean up your workspace, and leave the station ready for the next team.

**Conclusion**

This experiment presented the control of a temperature process loop. You became acquainted with the widely used open-loop Ziegler-Nichols tuning method.

**Review Questions**

1. What is the advantage of adding integral action to a proportional control scheme?

   A well-tuned integral action eliminates the offset typical of P-only control.

2. Why is on-off control not efficient in the experiment presented above?

   On-off control works well for slow-changing processes with large capacitance. In the experiment at hand, the temperature varies too quickly to be controlled by a two-state scheme.

3. Why does the trial-and-error method proceed with a factor of two change at every iteration?

   This method (geometrical progression) typically converges toward the solution faster than a fixed increment method (arithmetic progression).

4. What happens if you increase the $K_c$ parameter in a PI control scheme?

   The response will have a larger amplitude of oscillation and will take more time to stabilize.

5. Which process characteristic determines both the integral time and the derivative time when using the open-loop Ziegler-Nichols tuning method?

   The process dead time $r_d$
